DISTRIBUTION OF APOLLO 15 LUNAR SAMPLES

The National Aeronautics and Space Administration has begun general distribution to U.S. and foreign scientists of the largest and most varied collection of rocks and soil yet returned from the moon.

More than 2,200 Apollo 15 samples and polished thin sections weighing a total of about three kilograms (6.6 pounds) will be distributed to 201 principal investigators for study by them and their co-investigators during the next year.

Approximately 700 scientists in the United States, Virgin Islands, 15 foreign countries and one international body (European Space Research Organization) will take part in analyzing the material collected by Astronauts David R. Scott and James B. Irwin near Hadley Rille and the Apennine mountain front on the Moon last July.

CATEGORY 30

The scientific investigations will provide detailed information on the sample's mineralogy, petrology, chemistry, age and history and on the effects of micrometeorite impacts, solar radiation and cosmic ray bombardment.

Preliminary examination of samples in the Lunar Receiving Laboratory (LRL) at NASA's Manned Spacecraft Center, Houston, and studies of a small number of selected samples at other laboratories, show the Apollo 15 material to be of three types -- dark-colored, iron-rich basalts associated with mare and rille formation; a few basalts enriched in feldspar collected near the Apennine front; and light-colored, fragmental rocks or breccias consisting of soil-like materials which have been cemented together or of rock fragments which have been welded together by partial remelting.

The Apollo 15 material also contains several unique or unusual samples, some of which came from a small area on the Apennine front near Spur Crater. The samples collected at this site include a white crystalline rock called anorthosite, composed almost entirely of calcium-rich feldspar, and preliminary age dating shows it to be about 4 billion years old; a very interesting black-and-white rock containing light-colored fragments composed of feldspar-rich breccias and dark-colored fragments composed of basalt; a 1.1 kilogram (2.5 pound) breccia which has the lowest potassium content of any lunar sample; and several green rocks.

Other samples of special scientific interest include a 9.6 kilogram (21.2 pound) basalt which is the largest rock ever returned from the Moon; numerous particles of a unique, green glassy material which has been discovered in nearly every sample of Apollo 15 soil and which appears to be derived from a common source; and a sponge-textured basalt about the size of a grapefruit which is about sixty (60) per cent porous.

By studying the Apollo 15 samples, scientists hope to be able to characterize lunar rocks which formed prior to the filling of the mare basins. A number of samples, mainly composed of breccias from St. George and Spur Craters, along with several basaltic rocks, may be composed of material which formed before an asteroid-sized body is believed to have impacted the Moon, blasting out the basin which formed Mare Imbrium early in lunar history.

Soils and breccias collected near the lunar module are believed to contain ray materials from Aristillus or Autolycus, craters located on the eastern edge of Mare Imbrium which may penetrate through the mare fill to the underlying basement material.

Other studies may provide clues to the formation of rilles, the canyon-like depressions which extend for hundreds of kilometers across the lunar surface. And it is hoped ages can be obtained for some of the craters at the Apollo 15 site which would provide relative sequence of formation of features at the Hadley site.

More than fifty layers of lunar soil, collected in a 2.5 meter (2.72 yards) deep drill core, are expected to illuminate millions of years of lunar and solar history recorded in the stratigraphic sequence in much the same way as the history of a tree can be reconstructed from its growth rings. Small samples from ends of each of the six segments making up the drill stem will be distributed for reconnaissance study and will provide information which will assist in planning for a more comprehensive future study of this important and complex sample.

The samples to be distributed represent around four per cent of the 77 kilograms (170 pounds) of lunar material returned by Apollo 15. The remaining 96 per cent of the sample material will be stored at MSC under carefully controlled conditions for future study.

A total of 176 kilograms (388 pounds) of lunar material has been collected by the four U.S. lunar landing missions through Apollo 15. Of this total, 163 kilograms (359 pounds) are placed in reserve for future studies, for a time when new scientific instruments and concepts might become available.

Following is a list of principal investigators:

APOLLO 15 LUNAR SAMPLE ALLOCATION
